Qualcomm® Snapdragon™

# 7c Gen 2 Compute Platform

Qualcomm snapdragon

## Specifications & Features

### CPU
- CPU Clock Speed: Up to 2.55 GHz
- CPU Cores: Octa-core Qualcomm® Kryo™ 468 CPU
- CPU Architecture: 64-bit

### Process
- Process Technology: 8 nm

### OS Support
- Supports Windows 10 and Windows 11
- Chrome OS

### Memory
- Memory Type: 2 x 16-bit, LPDDR4x-4266

### Storage
- UFS: eMMC 5.1; UFS 2.1

### Visual Subsystem
- GPU: Qualcomm® Adreno™ GPU

### Camera
- Image Signal Processor: Qualcomm Spectra™ 255 image signal processor, 14-bit
- Dual Camera, ZSL, 30fps: Up to 16 MP

### Video
- Video Playback: Up to 4K HDR10
- Codec Support: H.265 (HEVC), H.264 (AVC), VP9
- Video Software: Motion Compensated Temporal Filtering (MCTF)

### Display
- Max On-Device Display: QXGA @ 60Hz, FHD @ 60Hz
- Max External Display: QHD @ 60Hz
- Display Pixels: 2560x1440, 2048x1536

### General Audio
- Qualcomm Aqstic technology: Qualcomm Aqstic™ audio codec, Qualcomm Aqstic smart speaker amplifier
- Qualcomm® aptX™ audio playback support: aptX, aptX HD

### Audio Playback
- PCM, Playback: Up to 384kHz/32bit
- Additional Playback Features: Native DSD support

### Qualcomm® AI Engine
- AIE CPU: Octa-core Kryo 468 CPU

- Uplink Technology: Qualcomm® Snapdragon™ Upload+
- Uplink Carrier Aggregation: 2x20 MHz carrier aggregation
- Uplink QAM: Up to 64-QAM
- LTE Speed
- LTE Peak Download Speed: 600 Mbps

### Wi-Fi
- Wi-Fi Standards: 802.11ac Wave 2, 802.11a/b/g, 802.11n
- Wi-Fi Spectral Bands: 2.4 GHz, 5 GHz
- MIMO Configuration: 2x2 (2-stream)
- Qualcomm® FastConnect™ Subsystem

### Bluetooth Version
- Bluetooth 5.0

### GPS Location
- Satellite Systems Support: NavIC, BeiDou, Galileo, GLONASS, GPS, QZSS, SBAS

### Security
- Qualcomm® Processor Security
- Qualcomm® Content Protection
- Wi-Fi Security: WPA3

**U.S. Patent No. 7,373,449 (Radulescu and Goossens)**
"Apparatus and method for communicating in an integrated circuit"

| '449 Patent Claim | Lenovo Product Including Snapdragon System on Chip[1] |
|---|---|

Camera

- Image Signal Processor: Qualcomm Spectra™ 255 image signal processor, 14-bit
- Dual Camera, ZSL, 30fps: Up to 16 MP
- Single Camera, ZSL, 30fps: Up to 32 MP
- Camera Features: Multi-frame Noise Reduction (MFNR)
- Video Capture Features: Rec. 2020 color gamut video capture, Up to 10-bit color depth video capture

CAMERA FEATURES

- Advanced DPD, WPA3
- Multi-Frame Noise Reduction (MFNR) and Multi-Frame Super Resolution (MFSR)
- Forward-looking Electronic Image Stabilization (EIS)
- Motion Compensated Temporal filtering (MCTF) for noise-free video capture up to UHD (4K) at 30 FPS
- Four MIPI CSI PHYs (DPHY 1.2 / CPHY 1.2)

- Additional Playback Features: Native DSD support

Qualcomm® AI Engine

- AIE CPU: Octa-core Kryo 468 CPU
- AIE GPU: Adreno GPU
- AIE DSP: Qualcomm® Hexagon™ 692 DSP

Cellular Modem

- Modem Name: Snapdragon X15 LTE modem
- LTE Category
- Downlink LTE Category: LTE Category 12
- Uplink LTE Category: LTE Category 13
- LTE Downlink Features
- Downlink Carrier Aggregation: 3x20 MHz carrier aggregation
- Downlink LTE MIMO: Up to 4x4 MIMO on two carriers
- Downlink QAM: Up to 256-QAM, Up to 64-QAM
- LTE Uplink Features

- Qualcomm® Processor Security
- Qualcomm® Content Protection
- Wi-Fi Security: WPA3

## Certain Arteris Technology Assets Acquired

by **Kurt Shuler**, on October 31, 2013

Arteris to continue to license, support and maintain Arteris FlexNoC® interconnect IP

SUNNYVALE, California — October 31, 2013 — Arteris Inc., a leading innovator and supplier of silicon-proven commercial network-on-chip (NoC) interconnect IP solutions, today announced that Qualcomm Technologies, Inc. ("Qualcomm"), a subsidiary of Qualcomm Incorporated, has acquired certain technology assets from Arteris and hired personnel formerly employed by Arteris.

> *Arteris NoC technology has been and will continue to be a key enabler for creating larger and more complex chips in a shorter amount of time at a lower cost. This acquisition of our technology assets represents a validation of the value of Arteris' Network-on-Chip interconnect IP technology.*

ARTERIS IP

*K. Charles Janac, President and CEO,* ***Arteris***

https://www.arteris.com/press-releases/Qualcomm-Arteris-asset-acquisition-2013_oct_31;
https://www.fiercewireless.com/tech/qualcomm-acquires-arteris-noc-tech-assets-team

The Arteris NoC exchanges messages in the Snapdragon SoC included in the Lenovo product.

For example, in the Arteris NoC, "[m]ost transactions require the following two-step transfers," including "[a] master send[ing] request packets" and "the slave return[ing] response packets":

| '449 Patent Claim | Lenovo Product Including Snapdragon System on Chip[1] |
|---|---|

### *11.3.1.1 Transaction Layer*

The transaction layer is compatible with bus-based transaction protocols used for on-chip communications. It is implemented in NIUs, which are at the boundary of the NoC, and translates between third-party and NTTP protocols. Most transactions require the following two-step transfers:

- A master sends request packets.
- Then, the slave returns response packets.

As shown in Figure 11.1, requests from an initiator are sent through the master NIU's transmit port, Tx, to the NoC request network, where they are routed to the corresponding slave NIU. Slave NIUs, upon reception of request packets on their receive ports, Rx, translate requests so that they comply with the protocol used by the target third-party IP node. When the target node responds, returning responses are again converted by the slave NIU into appropriate response packets, then delivered through the slave NIU's Tx port to the response network. The network then routes the response packets to the requesting master NIU, which forwards them to the initiator. At the transaction level, NIUs enable multiple protocols to coexist within the same NoC. From the point of view of the NTTP modules, different third-party protocols are just packets moving back and forth across the network.

**U.S. Patent No. 7,373,449 (Radulescu and Goossens)**
"Apparatus and method for communicating in an integrated circuit"

| '449 Patent Claim | Lenovo Product Including Snapdragon System on Chip[1] |
|---|---|
| | The Snapdragon SoC included in the Lenovo product utilizes the Arteris NoC to exchange messages over connections via a network, wherein said connections comprises a set of communication channels that are independently configurable.<br><br>For example, in the the Arteris NoC, "[a]n NTTP transaction is typically made of request packets, traveling through the request network between the master and the slave NIUs, and response packets that are exchanged between a slave NIU and a master NIU through the response network…. Transactions are handed off to the transport layer, which is responsible for delivering packets between endpoints of the NoC (using links, routers, muxes, rated adapters, FIFOs, etc.). Between NoC components, packets are physically transported as cells across various interfaces, a cell being a basic data unit being transported. This is illustrated in Figure 11.1, with one master and one slave node, and one router in the request and response path." |

| '449 Patent Claim | Lenovo Product Including Snapdragon System on Chip[1] |
|---|---|

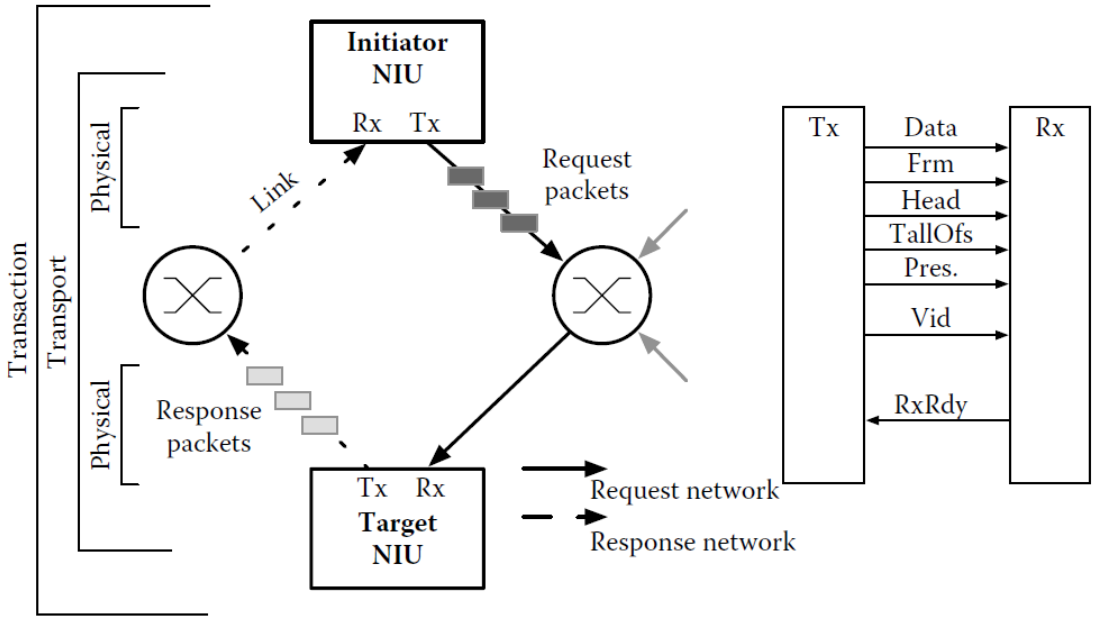

**FIGURE 11.1**
NTTP protocol layers mapped on NoC units and Media Independent NoC Interface—MINI.

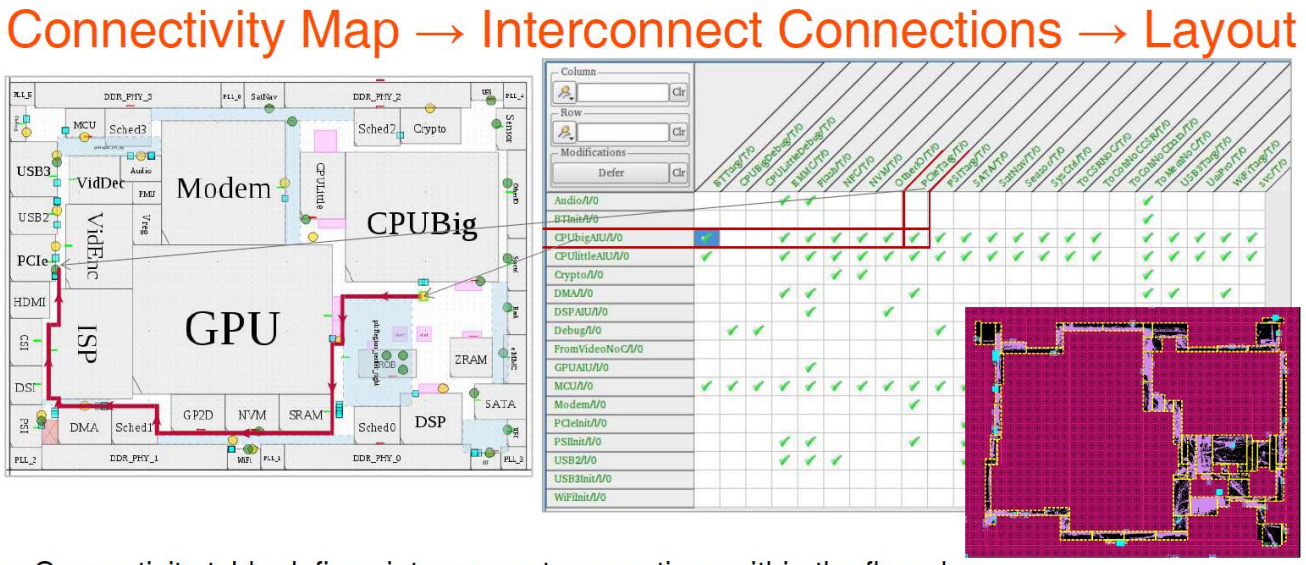
Connections within the Arteris NoC network may be defined by a connectivity table:

| '449 Patent Claim | Lenovo Product Including Snapdragon System on Chip[1] |
|---|---|



*See* Physical Interconnect Aware Network Optimizer, http://www.ispd.cc/slides/2018/s7_2.pdf, at slide 12.

In the Arteris NoC, "[t]he delivery of packets within the NoC is the responsibility of the physical layer [where the] link size, or width (i.e., number of wires), is set by the designer at design time[and] [o]ne link (represented in Figure 11.1) defines the following signals… Pres.—Indicates the current priority of the packet used to define preferred traffic class (or Quality of Service). The width is fixed during the design time, allowing multiple pressure levels within the same NoC instance (bits 3–5 in Figure 11.2) [and] RxRdy—flow control":

| '449 Patent Claim | Lenovo Product Including Snapdragon System on Chip[1] |
|---|---|
| | ***11.3.1.3 Physical Layer***<br>The delivery of packets within the NoC is the responsibility of the physical layer. Packets, which have been split by the transport layer into cells, are delivered as words that are sent along links. Within a single clock cycle, the physical layer may carry words comprising a fraction of a cell, a single cell, or multiple cells. The link size, or width (i.e., number of wires), is set by the designer at design time and determines the number of cells of one word. NTTP defines five possible link-widths: quarter (QRT), half (HLF), single (SGL), double (DBL), and quad (QUAD). A single-width (SGL) link transmits one cell per clock cycle, a double-width link transmits two cells per clock cycle, and so on. Words travel within point-to-point links, which are independent from other protocol layers: a word is sent through a transmit port, Tx, over a link to a receive port, Rx. The actual number of wires in a link depends on the |

maximum cell-width (header, necker, and data cell) and the link-width. One link (represented in Figure 11.1) defines the following signals:

- **Data**—Data word of the width specified at design-time.
- **Frm**—When asserted high, indicates that a packet is being transmitted.
- **Head**—When asserted high, indicates the current word contains a packet header. When the link-width is smaller than single (SGL), the header transmission is split into several word transfers. However, the Head signal is asserted during the first transfer only.
- **TailOfs**—Packet tail: when asserted high, indicates that the current word contains the last packet cell. When the link-width is smaller than single (SGL), the last cell transmission is split into several word transfers. However, the Tail signal is asserted during the first transfer only.
- **Pres.**—Indicates the current priority of the packet used to define preferred traffic class (or Quality of Service). The width is fixed during the design time, allowing multiple pressure levels within the same NoC instance (bits 3–5 in Figure 11.2).
- **Vld**—Data valid: when asserted high, indicates that a word is being transmitted.
- **RxRdy**—Flow control: when asserted high, the receiver is ready to accept word. When de-asserted, the receiver is busy.

This signal set, which constitutes the Media Independent NoC Interface (MINI), is the foundation for NTTP communications.

| '449 Patent Claim | Lenovo Product Including Snapdragon System on Chip[1] |
|---|---|
| | *See* Networks-On-Chips Theory and Practice, https://vdoc.pub/download/networks-on-chips-theory-and-practice-embedded-multi-core-systems-6f26qivv11f0, at 313-314.<br><br>The Snapdragon SoC included in the Lenovo product utilizes the Arteris NoC's connections that comprise a set of communication channels each having a set of connection properties, any communication channel being independently configurable.<br><br>For example, as noted above, in the Arteris NoC, "[o]ne link (represented in Figure 11.1) defines the following signals… Pres.—Indicates the current priority of the packet used to define preferred traffic class (or Quality of Service) [and] RxRdy—flow control."<br><br>In the Arteris NoC implements Quality of Service (QoS) to "provides a regulation mechanism allowing specification of guarantees on some of the parameters related to the traffic":<br><br>**Quality of Service (QoS).** The QoS is a very important feature in the interconnect infrastructures because it provides a regulation mechanism allowing specification of guarantees on some of the parameters related to the traffic. Usually the end users are looking for guarantees on bandwidth and/or end-to-end communication latency. Different mechanisms and strategies have been proposed in the literature. For instance, in Æthereal NoC [11,24] proposed by NXP, a TDMA approach allows the specification of two traffic categories [25]: BE and GT.<br>In the Arteris NoC, the QoS is achieved by exploiting the signal pressure embedded into the NTTP packet definition (Figures 11.1 and 11.2). The pressure |

| '449 Patent Claim | Lenovo Product Including Snapdragon System on Chip[1] |
|---|---|
| | signal can be generated by the IP itself and is typically linked to a certain level of urgency with which the transaction will have to be completed. For example, we can imagine associating the generation of the pressure signal when a certain threshold has been reached in the FIFO of the corresponding IP. This pressure information will be embedded in the NTTP packet at the NIU level: packets that have pressure bits equal to zero will be considered without QoS; packets with a nonzero value of the pressure bit will indicate preferred traffic class.* Such a QoS mechanism offers immediate service to the most urgent inputs and variables, and fair service whenever there are multiple contending inputs of equal urgency (BE). Within switches, arbitration decisions favor preferred packets and allocate remaining bandwidth (after preferred packets are served) fairly to contending packets. When there are contending preferred packets at the same pressure level, arbitration decisions among them are also fair.<br>The Arteris NoC supports the following four different traffic classes: |

| '449 Patent Claim | Lenovo Product Including Snapdragon System on Chip[1] |
|---|---|
| | • **Real time and low latency (RTLL)**—Traffic flows that require the lowest possible latency. Sometimes it is acceptable to have brief intervals of longer latency as long as the average latency is low. Care must be taken to avoid starving other traffic flows as a side effect of pursuing low latency.<br>• **Guaranteed throughput (GT)**—Traffic flows that must maintain their throughput over a relatively long time interval. The actual bandwidth needed can be highly variable even over long intervals. Dynamic pressure is employed for this traffic class.<br>• **Guaranteed bandwidth (GBW)**—Traffic flows that require a guaranteed amount of bandwidth over a relatively long time interval. Over short periods, the network may lag or lead in providing this bandwidth. Bandwidth meters may be inserted onto links in the NoC to regulate these flows, using either of the two methods. If the flow is assigned high pressure, the meter asserts backpressure (flow control) to prevent the flow from exceeding a maximum bandwidth. Alternatively, the meter can modulate the flows pressure (priority) dynamically as needed to maintain an average bandwidth.<br>• **Best effort (BE)**—Traffic flows that do not require guaranteed latency or throughput but have an expectation of fairness. |

| '449 Patent Claim | Lenovo Product Including Snapdragon System on Chip[1] |
|---|---|

* Note that in the NTTP packet, the pressure field allows more then one bit, resulting in multiple levels of preferred traffic.

Networks-On-Chips Theory and Practice, https://vdoc.pub/download/networks-on-chips-theory-and-practice-embedded-multi-core-systems-6f26qivv11f0, at 315-316.

As a further illustration, the Arteris NoC "addresses … varied QoS needs in many ways," including "Dynamic Packet Priorities" and "Dynamic Pressure Propagation":

## Arbitration: Dynamic Packet Priorities & Dynamic Pressure Propagation

Arteris Network on Chip technology addresses these varied QoS needs in many ways: First, the interconnect assigns priorities to transactions to ensure they arrive at the target in the proper order to meet system requirements. Priority levels can be attached to individual packets or to all transactions pending on a socket. The interconnect can also assign Dynamic Packet Priorities at runtime.

Second, the interconnect can sense when high priority packets may be blocked or slowed due to downstream traffic congestion and can then clear a path for these high priority packets. This technology, called Dynamic Pressure Propagation, is analogous to a fire truck racing down city streets: All traffic pulls to the side of the road to let the fire truck through.

https://www.arteris.com/end-to-end-quality-of-service-qos

| '449 Patent Claim | Lenovo Product Including Snapdragon System on Chip[1] |
|---|---|
| | As a further illustration, "QoS information may be generated from within the [Arteris] NoC interconnect using Arteris' QoS Generator":<br><br>Bandwidth Limiters and Rate Regulators<br><br>Many times architects will want to implement QoS within their SoC but the QoS prioritization data is not available from the individual IP blocks. In this case, QoS information may be generated from within the NoC interconnect using Arteris' QoS Generator. The QoS Generator can instantiate sophisticated, and software programmable, means to regulate interconnect QoS, including:<br><br>› Bandwidth Limiters – Bandwidth limiters cause a socket to stop accepting requests when a run-time programmable throughput threshold has been exceeded.<br>› Rate Regulators – Rate regulators cause a socket's transactions to be demoted when a bandwidth threshold is reached. This can be considered a smoother version of the bandwidth limiter because transactions are only demoted instead of stalled.<br><br>https://www.arteris.com/end-to-end-quality-of-service-qos<br><br>As a further illustration, the Arteris NoC uses "a mechanism called rated adaptation, which stalls packets just enough to remove wait states from the packets, preserving a low latency." For other traffic, the "[b]est effort traffic can be left untouched[,]" "[l]atency sensitive traffic may have its |

| '449 Patent Claim | Lenovo Product Including Snapdragon System on Chip[1] |
|---|---|
| | urgency modulated as a function of the transaction[,]" "[s]oft real-time traffic may have its hurry level modulated as a function of the bandwidth it receives[,]" and "[o]n the real-time modem data port, the hurry is fixed at a critical level":<br><br>Those effects can be mended by the insertion of buffering. In the case of peak bandwidth reduction, a simple FIFO does the job: Busy states present at the output of the FIFO do not propagate back to the input until the FIFO is full. For a peak bandwidth increase, the situation is a bit more complex. In a FIFO, wait states present at the input are only absorbed when the FIFO is not empty. Arteris proposes a mechanism called rate adaptation, which stalls packets just enough to remove wait states from the packets, preserving a low latency.<br>In this second step, the architecture is modified to introduce some buffering. In our example 760 bytes of memory have been distributed across the topology. Some have been put on existing links; some required the creation of new links.<br><br>See Application driven network-on-chip architecture exploration & refinement for a complex SoC, https://www.arteris.com/hs-fs/hub/48858/file-14363521-pdf/docs/springerappdrivennocarchitecture8.5x11.pdf, at pg.16.<br><br>For the other traffic, "the configuration can be done in architecture": |

| '449 Patent Claim | Lenovo Product Including Snapdragon System on Chip[1] |
|---|---|
| | • Best effort traffic can be left untouched.<br>• Latency sensitive traffic may have its urgency modulated as a function of the transaction: *Normal* for writes and *important* for reads.<br>• Soft real-time traffic may have its hurry level modulated as a function of the bandwidth it receives: *Critical* until a specified bandwidth is obtained on a sliding 4 microsecond window, and *normal* thereafter. These settings are set through configuration registers and may be modified while the interconnect is running. The mechanism is called a bandwidth regulator.<br>• On the real-time modem data port, the hurry is fixed at a critical level.<br><br>*Id.* at 18.<br><br>As a further illustration, connections within the Arteris NoC may be classified by traffic class and traffic classes may be mapped onto the Arteris interconnect topology: |

As a further illustration, in the Arteris NoC, "QoS is supported in the switch using pressure information generated by the IP itself and embedded in NTTP packets" and "[s]ome features [of the switch] can be software-controlled at runtime through the service network":

| '449 Patent Claim | Lenovo Product Including Snapdragon System on Chip[1] |
|---|---|
| | ***11.3.3.1 Switching***<br>The switching is done by accepting NTTP packets carried by input ports and forwarding each packet transparently to a specific output port. The switch is characterized with a fully synchronous operation and can be implemented as a full crossbar (up to one data word transfer per port and per cycle), although there is an automatic removal of hardware corresponding to unused input/output port connections (port depletion). The switch uses wormhole routing, for reduced latency, and can provide full throughput arbitration; that is, up to one routing decision per input port and per cycle. An arbitrary number of switches can be connected in cascade, supporting any loopless network topology. The QoS is supported in the switch using the pressure information generated by the IP itself and embedded in NTTP packets.<br>A switch can be configured to meet specific application requirements by setting the MINI-ports (Rx or Tx ports, as defined by the MINI interface introduced earlier) attributes, routing tables, arbitration mode, and pipelining strategy. Some of the features can be software-controlled at runtime through |

| '449 Patent Claim | Lenovo Product Including Snapdragon System on Chip[1] |
|---|---|
| | the service network. There is one routing table per Rx port and one arbiter per Tx port. Packet switching consists of the following four stages:<br><br>1. **Choosing the route**—Using relevant information extracted from the packet, the routing table selects a target output port.<br>2. **Arbitrating**—Because more than a single input port can request a given output port at a given time, an arbiter selects one requesting input port per output port. The arbiter maintains input/output connection until the packet completes its transit in the switch.<br>3. **Switching**—Once routing and arbitration decisions have been made, the switch transports each word of the packet from its input port to its output port. The switch implementation employs a full crossbar, ensuring that the switch does not contribute to congestion.<br>4. **Arbiter release**—Once the last word of a packet has been pipelined into the crossbar, the arbiter releases the output, making it available for other packets that may be waiting at other input ports.<br><br>The simplified block diagram of the switch architecture is shown in Figure 11.6. |

|---|---|
| | on their receive ports, Rx, translate requests so that they comply with the protocol used by the target third-party IP node. When the target node responds, returning responses are again converted by the slave NIU into appropriate response packets, then delivered through the slave NIU's Tx port to the response network. The network then routes the response packets to the requesting master NIU, which forwards them to the initiator. At the transaction level, NIUs enable multiple protocols to coexist within the same NoC. From the point of view of the NTTP modules, different third-party protocols are just packets moving back and forth across the network. |

The request issued by first module of the Snapdragon SoC included in the Lenovo product comprises desired connection properties associated with the sets of communication channels.

For example, in the Arteris NoC, "[t]he delivery of packets within the NoC is the responsibility of the physical layer [where the] link size, or width (i.e., number of wires), is set by the designer at design time[and] [o]ne link (represented in Figure 11.1) defines the following signals… Pres.—

| '449 Patent Claim | Lenovo Product Including Snapdragon System on Chip[1] |
|---|---|
| | Indicates the current priority of the packet used to define preferred traffic class (or Quality of Service). The width is fixed during the design time, allowing multiple pressure levels within the same NoC instance (bits 3–5 in Figure 11.2) [and] RxRdy—flow control":<br><br>***11.3.1.3 Physical Layer***<br><br>The delivery of packets within the NoC is the responsibility of the physical layer. Packets, which have been split by the transport layer into cells, are delivered as words that are sent along links. Within a single clock cycle, the physical layer may carry words comprising a fraction of a cell, a single cell, or multiple cells. The link size, or width (i.e., number of wires), is set by the designer at design time and determines the number of cells of one word. NTTP defines five possible link-widths: quarter (QRT), half (HLF), single (SGL), double (DBL), and quad (QUAD). A single-width (SGL) link transmits one cell per clock cycle, a double-width link transmits two cells per clock cycle, and so on. Words travel within point-to-point links, which are independent from other protocol layers: a word is sent through a transmit port, Tx, over a link to a receive port, Rx. The actual number of wires in a link depends on the |

maximum cell-width (header, necker, and data cell) and the link-width. One link (represented in Figure 11.1) defines the following signals:

- **Data**—Data word of the width specified at design-time.
- **Frm**—When asserted high, indicates that a packet is being transmitted.
- **Head**—When asserted high, indicates the current word contains a packet header. When the link-width is smaller than single (SGL), the header transmission is split into several word transfers. However, the Head signal is asserted during the first transfer only.
- **TailOfs**—Packet tail: when asserted high, indicates that the current word contains the last packet cell. When the link-width is smaller than single (SGL), the last cell transmission is split into several word transfers. However, the Tail signal is asserted during the first transfer only.
- **Pres.**—Indicates the current priority of the packet used to define preferred traffic class (or Quality of Service). The width is fixed during the design time, allowing multiple pressure levels within the same NoC instance (bits 3–5 in Figure 11.2).
- **Vld**—Data valid: when asserted high, indicates that a word is being transmitted.
- **RxRdy**—Flow control: when asserted high, the receiver is ready to accept word. When de-asserted, the receiver is busy.

This signal set, which constitutes the Media Independent NoC Interface (MINI), is the foundation for NTTP communications.

Usually the end users are looking for guarantees on bandwidth and/or end-to-end communication latency. Different mechanisms and strategies have been proposed in the literature. For instance, in Æthereal NoC [11,24] proposed by NXP, a TDMA approach allows the specification of two traffic categories [25]: BE and GT.<br>In the Arteris NoC, the QoS is achieved by exploiting the signal pressure embedded into the NTTP packet definition (Figures 11.1 and 11.2). The pressure |

| '449 Patent Claim | Lenovo Product Including Snapdragon System on Chip[1] |
|---|---|
| | signal can be generated by the IP itself and is typically linked to a certain level of urgency with which the transaction will have to be completed. For example, we can imagine associating the generation of the pressure signal when a certain threshold has been reached in the FIFO of the corresponding IP. This pressure information will be embedded in the NTTP packet at the NIU level: packets that have pressure bits equal to zero will be considered without QoS; packets with a nonzero value of the pressure bit will indicate preferred traffic class.* Such a QoS mechanism offers immediate service to the most urgent inputs and variables, and fair service whenever there are multiple contending inputs of equal urgency (BE). Within switches, arbitration decisions favor preferred packets and allocate remaining bandwidth (after preferred packets are served) fairly to contending packets. When there are contending preferred packets at the same pressure level, arbitration decisions among them are also fair.<br>The Arteris NoC supports the following four different traffic classes: |

| '449 Patent Claim | Lenovo Product Including Snapdragon System on Chip[1] |
|---|---|
| | • **Real time and low latency (RTLL)**—Traffic flows that require the lowest possible latency. Sometimes it is acceptable to have brief intervals of longer latency as long as the average latency is low. Care must be taken to avoid starving other traffic flows as a side effect of pursuing low latency.<br>• **Guaranteed throughput (GT)**—Traffic flows that must maintain their throughput over a relatively long time interval. The actual bandwidth needed can be highly variable even over long intervals. Dynamic pressure is employed for this traffic class.<br>• **Guaranteed bandwidth (GBW)**—Traffic flows that require a guaranteed amount of bandwidth over a relatively long time interval. Over short periods, the network may lag or lead in providing this bandwidth. Bandwidth meters may be inserted onto links in the NoC to regulate these flows, using either of the two methods. If the flow is assigned high pressure, the meter asserts backpressure (flow control) to prevent the flow from exceeding a maximum bandwidth. Alternatively, the meter can modulate the flows pressure (priority) dynamically as needed to maintain an average bandwidth.<br>• **Best effort (BE)**—Traffic flows that do not require guaranteed latency or throughput but have an expectation of fairness. |

| '449 Patent Claim | Lenovo Product Including Snapdragon System on Chip[1] |
|---|---|

* Note that in the NTTP packet, the pressure field allows more then one bit, resulting in multiple levels of preferred traffic.

As a further example, in the Arteris NoC, "QoS is supported in the switch using pressure information generated by the IP itself and embedded in NTTP packets"and the router architecture includes blocks such as "Input Controller," "Flow Control" and ""Crossbar (Flow control)":

| '449 Patent Claim | Lenovo Product Including Snapdragon System on Chip[1] |
|---|---|
| | ***11.3.3.1 Switching***<br>The switching is done by accepting NTTP packets carried by input ports and forwarding each packet transparently to a specific output port. The switch is characterized with a fully synchronous operation and can be implemented as a full crossbar (up to one data word transfer per port and per cycle), although there is an automatic removal of hardware corresponding to unused input/output port connections (port depletion). The switch uses wormhole routing, for reduced latency, and can provide full throughput arbitration; that is, up to one routing decision per input port and per cycle. An arbitrary number of switches can be connected in cascade, supporting any loopless network topology. The QoS is supported in the switch using the pressure information generated by the IP itself and embedded in NTTP packets.<br>A switch can be configured to meet specific application requirements by setting the MINI-ports (Rx or Tx ports, as defined by the MINI interface introduced earlier) attributes, routing tables, arbitration mode, and pipelining strategy. Some of the features can be software-controlled at runtime through |

| '449 Patent Claim | Lenovo Product Including Snapdragon System on Chip[1] |
|---|---|
| | the service network. There is one routing table per Rx port and one arbiter per Tx port. Packet switching consists of the following four stages:<br><br>1. **Choosing the route**—Using relevant information extracted from the packet, the routing table selects a target output port.<br>2. **Arbitrating**—Because more than a single input port can request a given output port at a given time, an arbiter selects one requesting input port per output port. The arbiter maintains input/output connection until the packet completes its transit in the switch.<br>3. **Switching**—Once routing and arbitration decisions have been made, the switch transports each word of the packet from its input port to its output port. The switch implementation employs a full crossbar, ensuring that the switch does not contribute to congestion.<br>4. **Arbiter release**—Once the last word of a packet has been pipelined into the crossbar, the arbiter releases the output, making it available for other packets that may be waiting at other input ports.<br><br>The simplified block diagram of the switch architecture is shown in Figure 11.6. |
